XBeach:

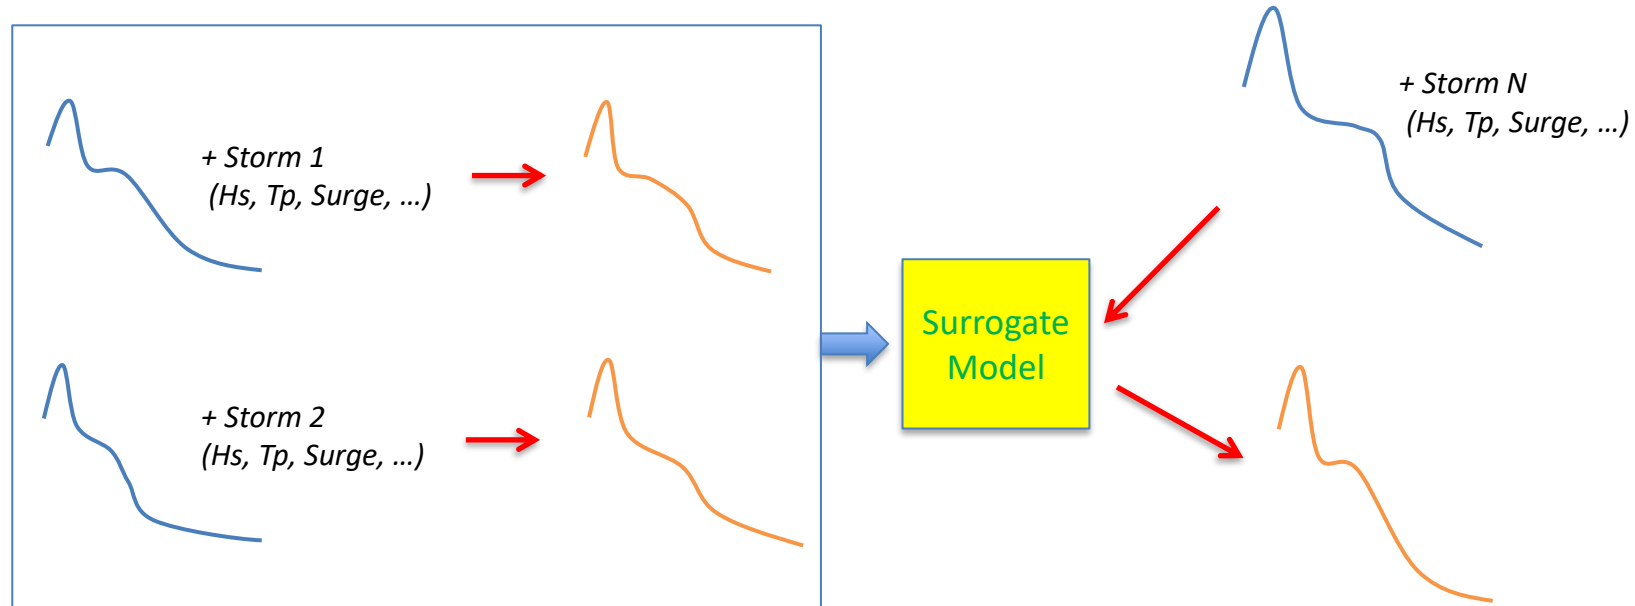

- The modeling tool is computationally expensive
- Not the best choice for predicting 1000s hypothetical scenarios

Therefore we combine statistic models with process-based model

Surrogate model:

Statistical model that learns how to predict like a process-based model using machine learning tools

Objectives:

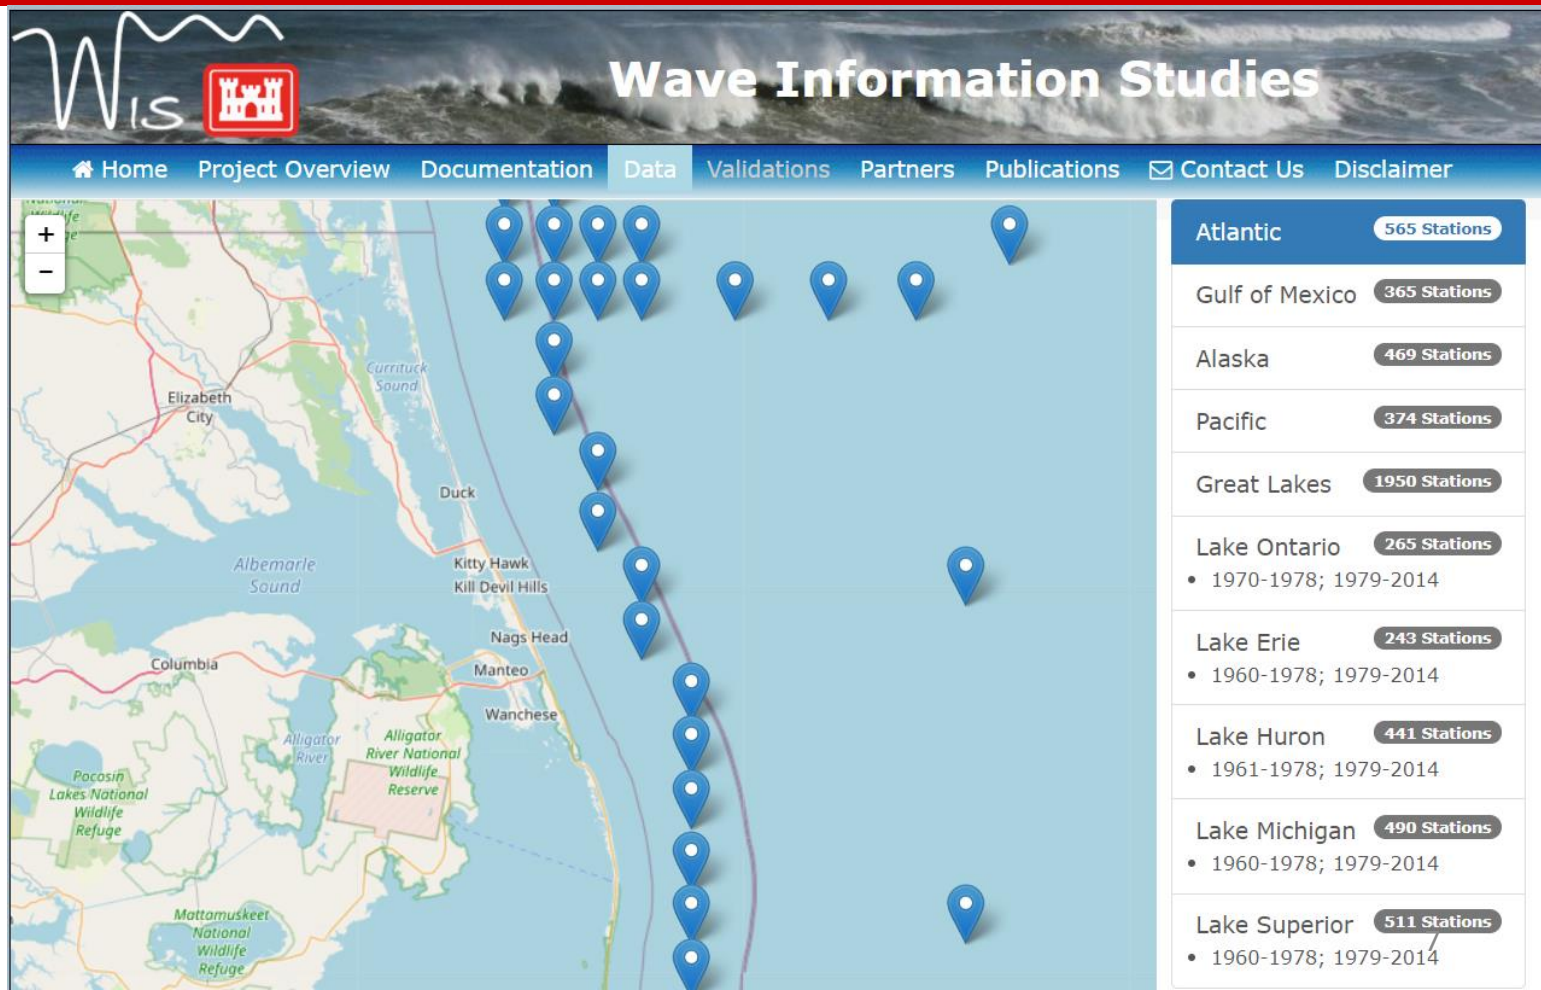

- Develop a surrogate model to predict nourishment retreat during storms
- Compile 1000s of storm data into possible future scenarios
- Parameterize beach geometry and the nourishment
- Develop a library of XBeach simulations using synthetic storms

Not just a surrogate for **storm** parameters To **beach/dune response** parameters

But **storm** + **initial beach/dune** parameters To **beach/dune response** parameters

We assess if a library of synthetic storms and idealized nourishment profiles produces an emulator with the ability to simulate realistic nourishment response to storm sequences.

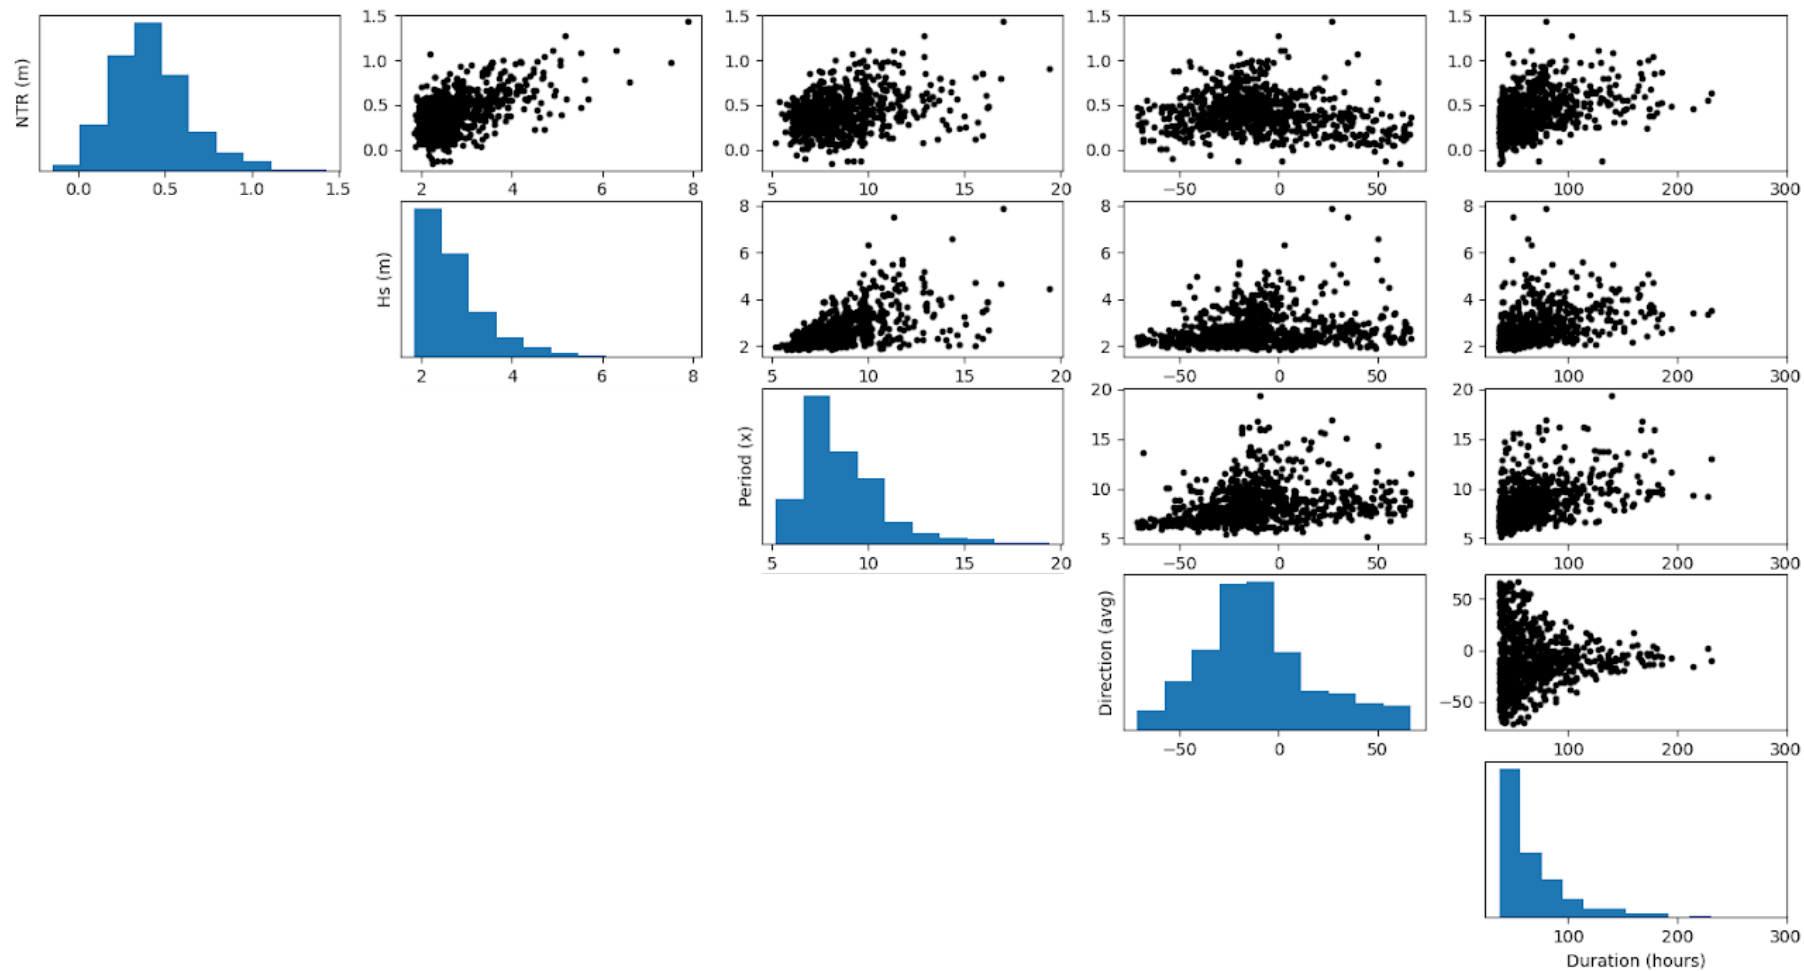

Inputs:
Storm data

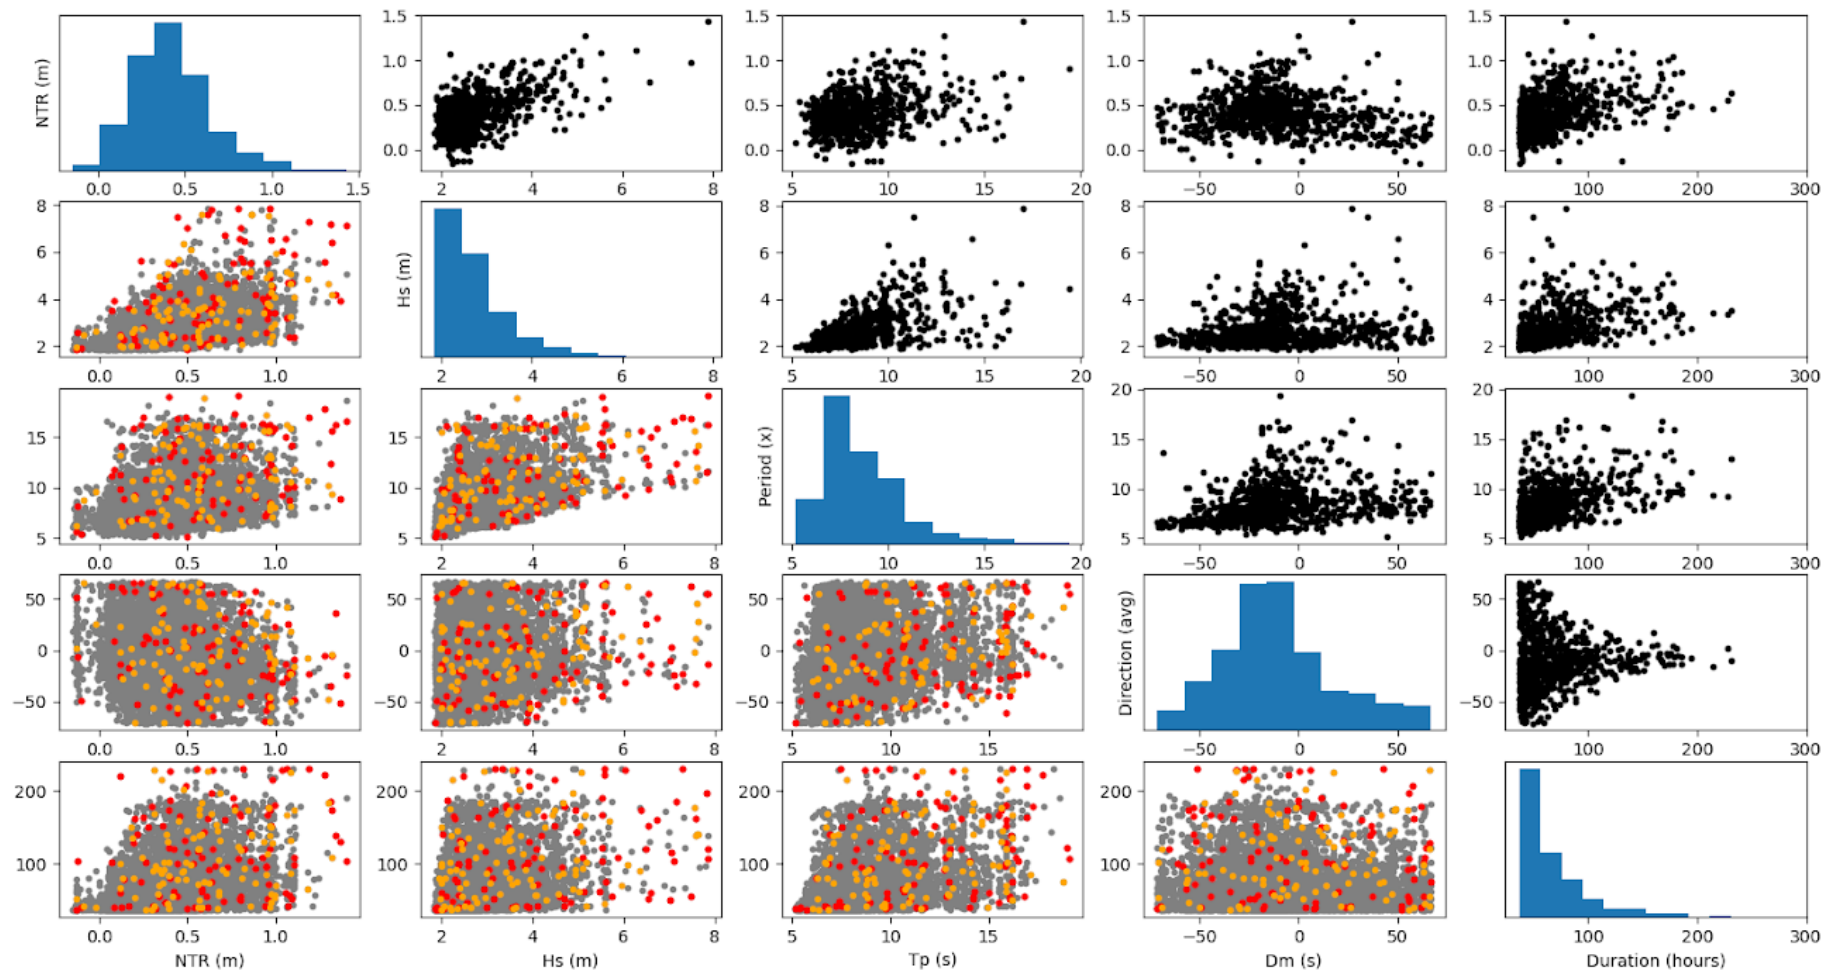

Inputs: Storm data

- Selecting storms
- Extracting parameters:
 - Hs
 - Tp
 - Theta
 - Surge
 - Duration

Nags Head, NC

- Over 15 surveys between 2010 & 2019
- Beach nourishment in 2011 & 2019

Inputs: beach profile data

- Interpolated surveys into DEM
- Extracted the Beach profile for each survey

Inputs: beach profile data

We use PCA to reduce dimensions

Modes of variability :

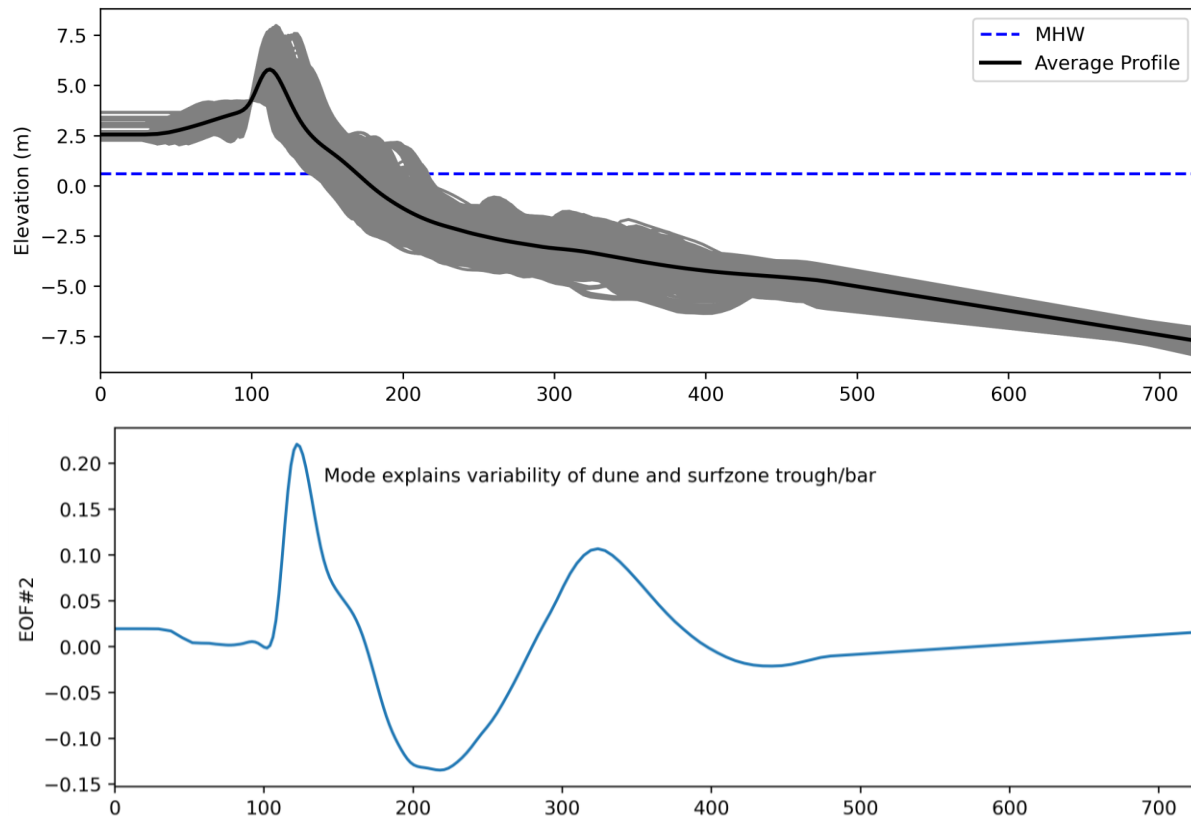

- Principal component #1
 - Dune
 - Beach

Inputs: beach profile data

Modes of variability :

- Principal component #2
 - Dune
 - Surf zone
 - Offshore bar

- Surrogate model predictions and comparison to XBeach

Conclusion

- The preliminary surrogate model results are encouraging
- We use the surrogate model to predict the erosion on the nourished beach during a sequence of hypothetical storms
- This can help to predict the frequency of required replenishment or amount of sediment needed for renourishment
- This is an ongoing work
- Need to expand the number of storms and profiles
- Need to add other parts of the emulator
